SOLAR POWERED DRIP IRRIGATION WITH RAIN WATER HARVESTING

*Prof.manjula¹, Ambika², Vasudha², Vaishnavi²

ABSTRACT

The project titled “Solar Powered Drip Irrigation System with Rainwater Harvesting” aims to design a smart and sustainable irrigation system that makes effective use of renewable energy and natural water resources. The main purpose of this project is to reduce dependence on conventional electricity, decrease water wastage, and introduce automation in agriculture with the help of modern technology.

In this system, solar energy acts as the primary power source. The solar panel converts sunlight into electrical energy, which is regulated using a charge controller and stored in a rechargeable battery. This stored energy is used to operate important system components such as sensors, a microcontroller, and a water pump, ensuring smooth and uninterrupted functioning even during non-sunny hours.

KEYWORDS: Solar Power, Drip Irrigation, Rainwater Harvesting, Water Conservation, Sustainable Agriculture, Solar Pumping System, Micro Irrigation, Smart Farming, Renewable Energy, Soil moisture monitoring, Efficient Water Management, Off-Grid irrigation, Eco-Friendly Farming, Irrigation Automation

1. INTRODUCTION

Water scarcity and unreliable electricity are major challenges faced by the agricultural sector, especially in rural and remote areas. To address these issues, a solar powered gravity drip irrigation system integrated with rainwater harvesting offers a sustainable and cost-effective solution. This system combines three key components: solar energy for water pumping, gravity-based drip irrigation, and rainwater collection and storage, ensuring efficient water management throughout the cropping season.

Rainwater harvesting plays a crucial role in this system by collecting and storing rainwater from rooftops or greenhouse coverings in storage tanks. This reduces dependence on external water sources and ensures water availability during dry periods. For instance, rainwater collected from plastic tunnel covers

can be directed into storage tanks through gutters. Properly sized tanks can store significant amounts of water—up to 6,400 liters per 100 square meters—providing sufficient irrigation water for most crops during their growth cycle.

The stored water is supplied to crops using a drip irrigation system powered by solar energy. Photovoltaic panels convert sunlight into electrical energy, which operates a water pump. The pump transfers water from the storage tank either to an elevated tank or directly into the irrigation lines.

When an elevated tank is used, gravity provides the necessary pressure for irrigation, eliminating the need for continuous power supply. This gravity-based approach is particularly beneficial in off-grid locations, as it reduces energy consumption, operational costs, and

maintenance requirements.

2. LITERATURE SURVEY

- [1] P. T. Jose and S. R. Sharma designed a low-cost, semi-automatic irrigation system aimed at rural households. Their design focused on simplicity, mechanical control, and affordability, using a basic pump and motor configuration. Their model emphasized mechanical control rather than electronic automation, reducing complexity and maintenance costs. The system consisted of a basic storage tank and motor, allowing effective watering with minimal power consumption. Their work demonstrated that even with limited resources, an effective irrigation mechanism could be achieved for rural communities.
- [2] R. Verma and A. Gupta explored the use of DC motors and L298N drivers for mechanical control in small appliances. They concluded that L298N drivers are efficient for controlling gear motors in compact systems. They investigated the application of DC motors for effective mechanical control in small home and field applications. They analyzed how L298N drivers efficiently manage the operation of motors, ensuring accurate direction and speed control. Their study focused on improving the compactness, performance, and energy efficiency of mechanical systems. The integration of the GSM module was a critical advancement, as it bridged the gap between the field and the farmer, providing a bridge for long-distance data transmission without the need for localized Wi-Fi infrastructure.
- [3] D. L. Prasad and R. Mehta introduced a solenoid valve control system for water inlets and drainage in small machines. Their work supported the idea of automated flow control using microcontrollers and valves. They introduced an innovative solenoid valve control system for managing water flow. Their design utilized a microcontroller-based automation approach, ensuring precise control of water flow during operation. By integrating solenoid valves, the system eliminated the need for manual operation, reducing water wastage.

3. EXISTING SYSTEM

The existing system for college transportation mainly relies on manual management and basic tracking

methods. In many colleges, students depend on fixed bus schedules without real-time location updates, which often leads to uncertainty and increased waiting time. Although some systems use GPS technology to track buses, they are limited to location monitoring only and do not provide additional safety features. In case of an accident, information is usually communicated manually by the driver or passengers, causing delays in emergency response. Moreover, there is no proper integration with emergency services, making it difficult to provide immediate assistance. Overall, the existing system lacks efficiency, real-time communication, and advanced safety mechanisms such as automatic accident detection and alert systems.

4. PROPOSED SYSTEM

The proposed system presents a sustainable and automated solution for agriculture by integrating solar-powered drip irrigation with rainwater harvesting. This system is designed to reduce dependency on conventional electricity and groundwater while ensuring efficient water usage for crops.

The system uses solar energy as the primary power source. Photovoltaic panels convert sunlight into electrical energy, which is used to operate a water pump. This pump draws water either from a storage tank or a rainwater harvesting unit and supplies it to the irrigation network. The use of solar energy makes the system eco-friendly, cost-effective, and suitable for rural or remote areas where electricity supply is unreliable.

Rainwater harvesting is incorporated to collect and store rainwater from rooftops or open catchment areas. The collected water is filtered and stored in a storage tank or reservoir. This stored water serves as an additional or backup water source, especially during dry periods, reducing the need for groundwater extraction.

The drip irrigation mechanism ensures that water is delivered directly to the root zone of plants through a network of pipes, valves, and emitters. This minimizes water wastage due to evaporation and runoff, improving water efficiency and crop productivity.

To enhance automation, soil moisture sensors are

installed in the field to monitor the moisture level of the soil in real time. Based on the sensor data, a controller automatically regulates the operation of the pump and the flow of water. When the soil moisture falls below a predefined threshold, the system activates irrigation, and it stops once the required moisture level is achieved.

Additionally, the system can include a simple monitoring interface (mobile or web-based) to allow farmers to track water levels, solar power generation, and irrigation status. This improves decision-making and reduces manual intervention.

5. METHODOLOGY

The fundamental working principle of this system is centered on the seamless integration of renewable energy harvesting and automated fluid dynamics to modernize traditional agricultural practices. The process begins at the 12V 5W Solar Panel, which captures solar radiation and converts it into a direct electrical current.

Fig. 1: BlockDiagram

The operational intelligence is governed by the ESP32 Controller with IoT capabilities, which serves as the central processing unit. This controller continuously monitors environmental variables through high-precision sensors, specifically the Soil Moisture Sensor and the DHT11 Sensor for temperature and humidity. When the volumetric water content in the soil drops below a pre-programmed threshold, the

ESP32 sends a signal to the L298N Driver.

This driver acts as the heavy-duty switch that activates the RS385 Water Pump, drawing water from the integrated Water Tank and delivering it precisely to the plant roots through a network of drip emitters.

6. WORKING

The integration of solar technology and automated irrigation creates a highly efficient, self-sustaining loop that minimizes human oversight while maximizing agricultural yield. The system's sustainability is anchored in its ability to harness ambient energy and water resources, effectively turning the farm into an autonomous ecosystem. Beyond the initial power conversion at the photovoltaic cells, the system employs a sophisticated power management strategy. The Charge Control unit not only prevents battery degradation by regulating the current but also ensures that the ESP32 Controller receives a surge-free, constant voltage, which is essential for maintaining the integrity of sensitive digital signals and Wi-Fi connectivity.

7. RESULTS AND CONCLUSION

The solar-powered drip irrigation system with rainwater harvesting successfully demonstrates how renewable energy and water conservation techniques can be combined for efficient agricultural use. As shown in the system layout and working model in the above figure, solar panels are used to power the water pump, while rainwater is collected and stored for irrigation purposes. This integration makes the system suitable for areas facing water scarcity and unreliable electricity supply.

The system provides controlled and uniform water delivery directly to the plant roots one through drip lines. This method significantly reduces water loss due to evaporation and runoff when compared to traditional irrigation methods. During operation, the solar panel supplied sufficient power to drive the pump under normal sunlight conditions, proving the effectiveness of solar energy for small-scale irrigation applications.

Fig. 2: Working Model

Rainwater harvesting played an important role in ensuring water availability, especially during dry periods. Stored rainwater can be effectively reused, reducing dependency on groundwater sources.

8. CONCLUSION

The solar-powered irrigation system with rainwater harvesting is an effective solution for water and energy management in agriculture. By using solar energy and collecting rainwater, the system reduces dependency on conventional electricity and groundwater sources.

It provides a reliable water supply to crops, especially in rural and remote areas where power availability is limited. This system helps in conserving

natural resources, reducing operational costs, and minimizing environmental impact. Overall, the project promotes sustainable farming practices and supports eco-friendly agricultural development.
