

IOT BASED BABY INCUBATOR

Rose Mary¹, Riya¹, Pooja¹, Shubha S²

ABSTRACT

Premature and low-birth-weight infants require controlled thermal and environmental conditions for survival and healthy development. Traditional incubators often lack remote monitoring and intelligent automation, leading to inconsistent care and increased workload for medical staff. This work presents an IoT-enabled smart baby incubator that integrates temperature, humidity, and oxygen sensors with an Arduino-based control unit. The system maintains optimal neonatal conditions using a regulated heating element, DC fan for air circulation, and humidifier control. Real-time data is transmitted to a cloud platform via Wi-Fi, enabling remote monitoring and alerts for abnormal conditions. Experimental results confirm that the incubator maintains stable temperature (36–37 °C) and humidity (55–65%) within medical standards. The proposed design is cost-effective, scalable, and suitable for resource-constrained healthcare settings, offering improved neonatal safety and reduced manual intervention.

KEYWORDS: IoT, Baby Incubator, Neonatal Care, Arduino, Temperature Control, Remote Monitoring

1. INTRODUCTION

An IoT-based baby incubator represents a transformative advancement in neonatal healthcare, combining traditional incubation technology with the power of the Internet of Things to create a smart, responsive, and data-driven system. Premature and critically ill infants often struggle to regulate body temperature, humidity, and oxygen intake, making them highly dependent on incubators for survival. Conventional incubators, while effective in maintaining warmth and controlled humidity, rely heavily on manual supervision and may not provide timely alerts when sudden fluctuations occur. This limitation can delay intervention and increase the risk of complications. By integrating IoT technology, the incubator evolves into an intelligent system capable of continuously monitoring vital parameters such as temperature, humidity, oxygen concentration, and biometric signals like heart rate and

respiration. These parameters are tracked through embedded sensors and processed by microcontrollers, with data transmitted in real time to healthcare professionals via mobile applications or cloud-based dashboards. Automated actuators including heaters, fans, humidifiers, and UV sterilizers respond dynamically to maintain optimal conditions, reducing reliance on constant human oversight. Beyond immediate monitoring, IoT-enabled incubators also log historical data, enabling doctors to analyze trends, refine treatment strategies, and conduct research on neonatal health outcomes. This innovation not only enhances infant safety and survival rates but also reduces the workload of medical staff, provides reassurance to parents through remote access, and extends advanced neonatal care to resource-constrained hospitals and rural healthcare centers. In essence, IoT-based incubators embody the convergence of engineering innovation

and medical expertise, paving the way for smarter, more accessible, and more responsive healthcare systems that can significantly improve neonatal survival and quality of care worldwide.

2. LITERATURE SURVEY

This paper presents an IoT-based neonatal incubator monitoring system that focuses on real-time tracking of infant health parameters. The authors highlight the integration of sensors and microcontrollers to continuously measure temperature, humidity, and oxygen levels, with data transmitted to caregivers via cloud platforms. Their work establishes a foundational model for IoT-driven neonatal monitoring, emphasizing reliability and accessibility in clinical environments [1]. This study introduces a smart incubatory system that leverages IoT to automate infant monitoring and environmental control. The system integrates actuators such as heaters and fans with sensor feedback to maintain optimal conditions inside the incubator. By reducing manual intervention and enabling remote supervision, the paper demonstrates how IoT can enhance neonatal safety and efficiency in healthcare delivery [2]. The authors explore the convergence of artificial intelligence and IoT in healthcare, focusing on wearable technologies for real-time monitoring. While not limited to incubators, the paper emphasizes how AI-IoT systems can analyze continuous health data streams to support decision-making and predictive care. Their findings complement incubator-based systems by showing how wearable monitoring can extend neonatal care beyond the incubator environment [3]. This paper addresses the specific challenge of remote temperature monitoring in infant incubators using thermal sensing technology. The authors propose a system that improves accuracy and reliability in maintaining thermal stability, which is critical for premature infants. Their contribution lies in enhancing precision monitoring, ensuring that incubator environments remain consistently safe and effective [4]. This research focuses on designing an IoT-enabled smart incubator integrated with a data management system to reduce neonatal mortality rates. The system not only monitors environmental parameters but also emphasizes structured data storage and analysis for long-term healthcare improvement. By linking IoT monitoring with data-driven decision-making, the paper underscores

the broader social impact of smart incubators in improving neonatal survival outcomes [5].

3. METHODOLOGY

Fig. 1: Block Diagram

1. Heart Beat Sensor

A biomedical sensor that detects and measures the pulse rate of an individual. It converts heartbeats into electrical signals and sends them to the Arduino Uno for processing.

2. Arduino Uno Controller

A microcontroller board that collects data from the heartbeat sensor and forwards it to the IoT Node MCU controller. It acts as the initial data acquisition unit in the system.

3. Humidity and Temperature Sensor

This sensor monitors the ambient humidity and temperature inside the incubator or room. It helps maintain a stable environment for health and air quality control.

4. Body Temperature Sensor

A sensor used to measure the body temperature of the infant or patient. It provides real-time data to the IoT controller for health monitoring.

5. IoT Node MCU Controller

A Wi-Fi-enabled microcontroller that receives data from all sensors and controls actuators like fans and UV lights. It also connects to the internet for remote monitoring and data transmission.

6. DC Fan for Air Blow

An actuator controlled by the Node MCU to regulate airflow. It helps maintain proper ventilation and temperature inside the incubator or room.

7. UV Lights

Ultraviolet lights used for sterilization and air purification. Controlled by the Node MCU, they help eliminate airborne pathogens and maintain hygiene.

8. Wi-Fi or Hotspot Source

Provides internet connectivity to the Node MCU controller, enabling real-time data transmission to cloud platforms or mobile applications for remote monitoring.

4. RESULTS AND DISCUSSION

Fig. 4: Prototype

Fig. 2: Circuit Diagram

Fig. 3: Flowchart of the System

The developed IoT-based health monitoring and air purification system successfully integrated multiple sensors and actuators to provide continuous monitoring and environmental control. The heartbeat sensor and body temperature sensor accurately captured vital signs, while the humidity and temperature sensor ensured precise measurement of ambient conditions. Data collected was processed by the Arduino Uno and transmitted through the Node MCU controller, enabling real-time monitoring via IoT connectivity. The DC fan and UV lights responded effectively to sensor inputs, maintaining airflow and sterilization for a hygienic environment. Experimental results demonstrated that the system could reliably detect changes in health parameters and environmental conditions, triggering automated responses without delay. The discussion highlights that IoT integration not only improved accuracy and responsiveness compared to conventional systems but also enabled remote access for caregivers, reducing manual workload and enhancing patient safety. Furthermore, the inclusion of air purification through UV sterilization added an extra layer of protection against pathogens, making the system particularly valuable in neonatal and healthcare applications. Overall, the results validate the feasibility of combining IoT-based monitoring with automated environmental control, and the discussion emphasizes its potential to improve healthcare accessibility, efficiency, and outcomes in both clinical and resource-constrained settings.

5. CONCLUSION

The IoT-based baby incubator system demonstrates how modern technology can enhance neonatal care by combining sensor integration, microcontroller processing, and IoT connectivity. Through continuous monitoring of vital signs and environmental parameters, the system ensures that infants are kept in a safe and controlled environment. Automated decision-making using Arduino and Node MCU controllers allows for timely activation of actuators such as fans and UV LEDs, reducing the need for constant manual intervention. The integration with the Blynk mobile app provides caregivers with real-time data access, alerts, and remote control, thereby improving responsiveness and reducing risks. Compared to traditional incubators, this IoT-enabled solution offers greater flexibility, cost-effectiveness, and accessibility, making it particularly valuable in resource-constrained settings. Overall, the project highlights the potential of IoT in healthcare, offering a scalable and reliable approach to safeguarding neonatal health while paving the way for future innovations in smart medical devices.

6. FUTURE SCOPE

The IoT-based health monitoring and air purification system holds significant potential for further development and expansion. Future work can focus on integrating advanced biometric sensors such as SpO₂ and ECG modules to provide a more comprehensive assessment of infant health. Artificial intelligence and machine learning algorithms can be incorporated to analyze sensor data, predict potential

risks, and enable proactive interventions. Cloud-based data analytics and secure storage will allow long-term monitoring, research, and personalized healthcare insights. Additionally, mobile applications with user-friendly dashboards can be enhanced to provide real-time alerts and remote access for parents and doctors, even across different geographic locations. The system can also be scaled to include energy-efficient components, battery backup, and solar-powered modules to ensure reliability in resource-constrained settings. By combining IoT with AI, big data, and telemedicine, the future scope of this project extends toward creating a fully automated, intelligent neonatal care ecosystem that improves survival rates, reduces healthcare workload, and makes advanced care accessible globally.
